

Slides for Discussion of Issue 2: Risk of Bias

Joyce S. Tsuji, Ph.D., DABT, Fellow ATS

Vanessa Perez, Ph.D.

Michael Garry, Ph.D.

Systematic Review and Evaluation for Risk Assessment (RA)

- Criteria for RA: Dose metric, risk estimate, low-level exposure
- Study Design: Case-control or cohort more powerful than cross-sectional or ecological
- Analysis: evaluation of confounders/effect modifiers/mediators
- Quality assessment: participation/attrition rate, exposure specific to iAs, outcome assessment, length of follow-up, completeness & transparency of analysis
- Evaluation of the overall evidence regarding dose-response, including review/analysis articles

Confounders and Effect Modifiers: Nutrients in One-Carbon Metabolism and Health Outcomes

High homocysteine and low folate levels are associated with increased CVD risk independent of As (McNulty et al. 2012; Wang et al. 2012)

Effect of Homocysteine on 1) Methylation of Arsenic and Other Substrates, 2) Disease Risk

Low folate and high SAH/homocysteine suppress methylation of arsenic and other important substrates

As^{III}—trivalent inorganic arsenic; As3MT—arsenite methyltransferase; DMA^V—pentavalent dimethylarsinic acid; DNA MT—DNA methyltransferase; GA—guanidinoacetate; GAMT—guanidinoacetate methyltransferase; MMA—monomethylarsonic acid; SAH—S-adenosylhomocysteine; SAM—S-adenosylmethionine

Geographic Distribution of Betel (Areca) Nut Use (e.g., Bangladesh, India, Taiwan)

- Reduces folate status
- Increases risk of skin lesions (Pilsner et al. 2009)
- Various health risks (heart/respiratory disease, diabetes, reproductive effects, cancer (Islam and Majumder 2013; McClintock et al. 2014; WHO 2012))
- Synergistic effect with smoking
- Enhances apparent association of arsenic with these diseases
